PREFACE

This volume of the annual hydrologic data report of Wisconsin is one of a series of annual reports that document hydrologic data gathered from the U.S. Geological Survey's surface- and ground-water data-collection networks in each State, Puerto Rico, and the Trust Territories. These records of streamflow, ground-water levels, and water quality provide the hydrologic information needed by State, local, and Federal agencies, and the private sector for developing and managing our Nation's land and water resources.

This report is the culmination of a concerted effort by dedicated personnel of the U.S. Geological Survey who collected, compiled, analyzed, verified, and organized the data, and who typed, edited, and assembled the report. The authors had primary responsibility for assuring that the information contained herein is accurate, complete, and adheres to Geological Survey policy and established guidelines. Most of the data were collected, computed and processed from area field offices. Technicians-in-charge of the field offices are:

Jack T. Freshwaters, Rice Lake, northwest
James W. George, Merrill, northeast
Josef Habale, Madison, southwest
Fredren E. Warner, Wales, subdistrict office

The data were collected, computed, and processed by the following personnel:

This report was prepared in cooperation with the state of Wisconsin and with other agencies under the general supervision of Warren A. Gebert, Hydrologic Systems and Data Section Chief; Thomas G. Ross, Subdistrict Office Chief; and Vernon W. Norman, District Chief, Wisconsin.

WATER RESOURCES DATA FOR WISCONSIN, 1982

INTRODUCTION

Wisconsin water-resources data for the 1982 water year include records of streamflow at gaging stations, partial-record stations, and miscellaneous sites; chemical, physical, and biological characteristics of surface and ground water; and water levels in observation wells. Records from several stations in bordering states also are included. Data collection is part of the National Water Data System operated in Wisconsin by the U.S. Geological Survey and cooperating State and Federal agencies.

Records of stream discharges and of water levels in lakes and reservoirs were published annually through 1960 and then for the 5-year periods 1961-65 and 1966-70 in the series "Surface-Water Supply of the United States". Chemical-quality, water-temperature, and suspended-sediment data were published annually, from 1941 to 1970, in the series "Quality of Surface Waters of the United States". Records of ground-water levels were published annually from 1935 to 1974, in the series "Ground-Water Levels in the United States".

With the 1961 water year, the Survey began releasing preliminary streamflow data on a State-by-State basis, preliminary water-quality data from the 1964 water year on, and preliminary ground-water data since the 1971 water year. Final data then were published in the series mentioned above. Beginning with the 1975 water year, streamflow, water-quality, and ground-water data for each State were published in a single yearly report and are for sale, in paper copy or in microfiche, by the National Technical Information Service, U.S. Department of Commerce, Springfield, VA 22161.

COOPERATION

The U.S. Geological Survey and the State of Wisconsin have worked under cooperative agreements since 1913 collecting streamflow data, since 1955 collecting water-quality data, and since 1964 recording ground-water levels. Agencies that worked cooperatively with the Survey during this year collecting data are:

Wisconsin Department of Natural Resources, C. D. Besadny, secretary.

Wisconsin Department of Transportation, Owen Ayres, secretary,
and S. W. Woods, chief bridge engineer.

The University of Wisconsin-Extension, Geological and Natural
History Survey, M. E. Ostrom, state geologist and director.

Dane County Department of Public Works, Kenneth J. Koscik,
director.

Dane County Regional Planning Commission, Charles Montemayor,
executive director.

Southeastern Wisconsin Regional Planning Commission, K. W. Bauer, executive director.

City of Middleton, Dan Ramsey, mayor.

City of Madison, A. E. Milke, city engineer.

Madison Metropolitan Sewerage District, James L. Nemke, chief engineer and director.

Madison Water Utility, Gary Graham, manager.

Town of Schleswig, Dennis Robichaud, chairman.

Sokaogon Chippewa Community, Arlyn Ackley, chairman.

Menominee Indian Tribe of Wisconsin, Lucille B. Chapman, chairperson.

Lac Courte Oreilles Governing Board, Gordon Thayer, president.

Funding for the collection of streamflow and/or water-quality data was provided by the Corps of Engineers, U.S. Army, the National Park Service, and the Bureau of Indian Affairs.

The following organizations aided in collecting streamflow records:

Wisconsin Valley Improvement Co., Lake Superior District Power Co., Wisconsin-Michigan Power Co., Wisconsin Public Service Corp., Northern States Power Co., Dairyland Power Cooperative, Wisconsin Power and Light Co., Nekoosa Papers Inc., Wisconsin Electric Power Co., Wisconsin River Power Co., and Milwaukee County Park Commission.

Organizations that supplied data are acknowledged in station descriptions.

SPECIAL NETWORKS AND PROGRAMS

Hydrologic Bench-Mark Program provides data for river basins where hydrologic conditions are relatively unaffected by man's activities and will remain unaffected within the foreseeable future.

National Stream-Quality Accounting Network was designed by the U.S. Geological Survey to meet information needs of agencies or groups involved in national or regional water-quality planning and management. Both accounting and broad monitoring aspects have been incorporated in the network design. The network is divided according to the river-basin accounting units designated by the Office of Water Data Coordination in consultation with the Water Resources Council. Primary objectives of the network are: (1) to assess the areal variability of water-quality conditions nationwide on an annual basis; and (2) to assess long-term changes in stream quality.

Radiochemical surveillance network of water-quality stations, representing major drainage basins in the conterminous United States, where samples are collected regularly for radioisotope analysis.

DOWNSTREAM ORDER AND STATION NUMBER

Hydrologic-station records are listed in Survey reports in downstream direction along streams. Each gaging, partial-record, and surface-water quality station is identified by an 8-digit number. Records in this report are in Part 4 (St. Lawrence River basin) and Part 5 (Upper Mississippi River basin).

NUMBERING SYSTEM FOR GROUND-WATER DATA SITES

The unique ground-water data-site number, based on latitude and longitude, indicates the geographic location of a well. Each site also is identified by a local number based on the cadastral-survey system of the U.S. Government. The number consists of an abbreviation of the county name, the township, range, and section, and a four-digit number assigned to the well.

EXPLANATION OF SURFACE-WATER RECORDS

COLLECTION AND COMPUTATION OF DATA

The basic data collected at gaging stations include stage and discharge measurements of streams, surface-area and stage, measurements of lakes. In addition, factors affecting stage-discharge relationships, weather records, and other information supplement the basic data used to determine daily flow. Records of stage are obtained by reading a non-recording gage, from a continuous graph, or from a tape punched at selected intervals on a water-stage recorder. Measurements of discharge are made with a current meter using methods described in standard textbooks, in Water-Supply Papers 888 and 2175, and in Techniques of Water Resources Investigations of the United States Geological Survey, book 3, chapter A6.

Rating tables of the discharge for any stage are prepared from stage-discharge relationship curves. Extended rating curves, based on step-backwater techniques, velocity-area studies, logarithmic plotting, and indirect measurements of peak discharge are used to estimate discharges greater than those measured. Daily mean discharges are computed from gage heights and rating tables, and the monthly and yearly means are computed using the daily figures. If the stage-discharge relationship varies due to changes in the control, such as aquatic growth, debris, or scour and fill, daily mean discharge is computed by a shifting-control method in which correction factors, based on individual discharge measurements and notes by observers, are used when the gage heights are applied to the rating tables.

At stream-gaging stations where backwater from lakes or reservoirs, tributary streams, or other sources affects the stage-discharge relationship, the slope method is used to compute discharge. At stations where the stage-discharge relationship is affected by rapid changes in stage, the rate of change is used in computing discharge. When ice conditions at stream-gaging stations affect the stage-discharge relationship, gage-height records, winter discharge measurements, temperature and precipitation data, and comparable records of discharge for nearby stations are used to compute discharge. At gaging stations where gage-height records are faulty or non-existent for some periods, the daily discharges are estimated based on the recorded range in stage, prior and subsequent records, discharge measurements, weather records, and comparison with records for nearby stations.

Included in this report are descriptions of the stations and tabulations of data. A table showing daily, monthly, and yearly discharges is given for each gaging station on a stream or canal. A table showing the monthly summary table of stage is given for gaging stations on lakes. Records are for a water year, which begins October 1 and ends September 30.

The description of the gaging station includes the location, drainage area, period of record, revisions in previously published records, the type and history of gages, general remarks, average discharge, and extremes of discharge or contents. River mileage is determined by the Corps of Engineers or other agencies. Previously published records for current stations are noted under "PERIOD OF RECORD". Previously published revisions of stream-flow records found in error on the basis of subsequent data are noted under "REVISED RECORDS". Listed therein are all the reports in which revisions have been published, together with the water years for which figures are revised. Revisions involving only the instantaneous maximum and minimum, and supplementary peak discharges are indicated by "(M)", "(m)", or "(P)", respectively. If the drainage area has been revised, the report in which the revised figure was first published is given.

The type of gage currently in use; the datum of the present gage referred to National Geodetic Vertical Datum of 1929; and a history of the types, locations, and datums of previous gages used during the period of record are given under "GAGE."

Information pertaining to the accuracy of discharge records and to conditions that affect the natural flow at the gaging station is given under "REMARKS".

The average discharge for the period of record is given under "AVERAGE DISCHARGE". For stations having fewer than 5 complete years of record or where water development during the period of record has altered the significance of the figure, average discharge is not given. Under "EXTREMES" are listed the extremes of discharge for the period of record, discharge information available outside the period of record, and discharge data for the current year. Unless otherwise qualified, maximum discharge is the instantaneous maximum corresponding to the stage recorded by a water-stage recorder, a crest-stage gage, or a nonrecording gage read at the time of the crest. If the maximum gage height did not occur on the same day as the

maximum discharge, it is listed separately. Similarly, the minimum discharge is the instantaneous minimum corresponding to the minimum recorded stage. Independent peak discharges above a selected base, including the annual maximum, together with the time of occurrence and corresponding gage heights are listed with "EXTREMES FOR THE CURRENT YEAR" for some stations. The base discharge is selected so as to present about three peaks a year. Peak discharges are not published for canals, ditches, drains, or for any stream subject to substantial control by man. Minimum discharges for these stations appear in a separate paragraph following the table of peaks. Skeleton rating tables are published for stations where they serve a useful purpose immediately following "EXTREMES".

The daily table for stream-gaging stations gives the daily mean discharges and monthly and yearly summaries. In the monthly summary "TOTAL" is the sum of the daily figures; "MEAN" is the average monthly flow in cubic feet per second (ft^3/s). "MAX" and "MIN" are the maximum and minimum daily discharges, respectively, for the month. The monthly discharge also is expressed in cubic feet per second per square mile ("CFSM"), in inches ("IN"), and in acre-feet ("AC-FT"). CFSM and IN are omitted if there is extensive regulation or diversion, if the drainage area encompasses large noncontributing areas, or if average annual precipitation for the drainage basin is usually less than 20 inches. The annual summary shows appropriate daily discharges for the calendar and water years.

Footnotes to the daily-discharge table indicate periods for which discharge is computed or estimated by special methods because of the absence of gage-height records, backwater from various sources, or other unusual conditions; periods of no gage-height record if the period is continuous for a month or more or if the maximum annual discharge occurs during that time. Periods of backwater from sources other than ice are indicated only if they last for a month or more, thus affecting the accuracy of the discharge records.

The data presented for most gaging stations on lakes include a description of the station and a monthly summary table of stage.

Data collected at crest-stage partial-record stations are given in a table of annual maximum stages and discharges. Occasionally, a short series of discharge measurements are made to investigate seepage gains or losses along a reach of stream or to determine the low-flow characteristics of an area. Miscellaneous measurements follow the tables for partial-record stations.

ACCURACY OF FIELD DATA AND COMPUTED RESULTS

Accurate streamflow data depend primarily on the stability of the stage-discharge relation or the frequency of discharge measurements, where the control is unstable; and the accuracy of discharge measurements, observations of stage, and interpretation of records.

The accuracy of the records is given under "REMARKS". "Excellent" means that about 95 percent of the daily discharges are accurate within 5 percent; those accurate within 10 percent are termed "good"; and "fair" indicates records accurate within 15 percent. "Poor" means that daily discharges have less than "fair" accuracy.

Discharge figures in this report are rounded to the nearest hundredth for discharges of less than 1 ft³/s; to the nearest tenth for discharges between 1.0 and 10 ft³/s; to the nearest whole number for discharges between 10 and 1,000 ft³/s; and to 3 significant figures for discharges above 1,000 ft³/s.

OTHER DATA AVAILABLE

For most gaging stations more detailed information is on file in the District Office. Also, most gaging-station records are available in computer-usable form, and many statistical analyses have been made.

EXPLANATION OF WATER-QUALITY RECORDS

COLLECTION AND EXAMINATION OF DATA

Surface-water samples usually are collected at or near gaging stations. The water-quality records appear after the discharge records for these stations.

The descriptive heading for water-quality records gives the period of record for all water-quality data, the period of record for characteristics and properties that are measured daily, general remarks, extremes for the period of daily record, and extremes for the current year.

For ground-water-quality records, the well number, depth of well, aquifer, date of sampling and other pertinent data are given in the table containing the chemical analyses.

WATER ANALYSIS

Methods for collecting and analyzing water samples are described in Techniques of Water-Resources Investigations of the United States Geological Survey.

One sample can define adequately the water quality at a given time if the mixture of materials throughout the stream cross section is homogeneous. However, their concentration at different locations in the cross section usually differ widely depending on the source of the material, the turbulence and mixing of the stream, and rate of water discharge. Most streams must be sampled at several verticals in a cross section to obtain a representative sample.

The water-quality data published in this report represent conditions at the time of sampling. The concentrations of some constituents are given as less than some value; that value is the detection limit for the analytical method used. Occasionally these values differ or an actual concentration given which is less than a higher detection limit for a constituent. These differences or apparent discrepancies are due to different methods being used for the constituents.

For water-quality stations equipped with monitors, the records include daily maximum, minimum, and mean values for each characteristic and property measured hourly. Hourly values may be obtained from the District Office. At stations where once-daily measurements are taken manually the measurements usually are taken at about the same time each day.

SEDIMENT

Suspended-sediment concentrations are determined from samples collected with depth-integrating samplers at several verticals in the cross section, or a single sample taken at a fixed point manually, or with pumping samplers (a coefficient is applied to it to determine the mean concentration throughout the cross section).

During periods of rapidly changing flow or concentration, sediment samples may be collected more frequently. The published suspended-sediment discharges for these periods were computed by the subdivided-day method (time-discharge weighted average). For periods when no samples were collected, daily suspended-sediment discharges were estimated on the basis of water discharge, suspended-sediment concentrations observed immediately before and after the periods, and suspended-sediment discharge for other periods of similar discharge. The accuracy of sediment records, discussed under "REMARKS", is based on completeness of the record, the number of samples collected, and the range in stage over which samples are collected. Suspended-sediment discharges of less than 0.005 tons/day are reported as 0.

Samples collected periodically may represent conditions only at the time of observation. However, they are useful in determining seasonal relationships between water quality and streamflow, and in predicting long-term suspended-sediment discharge characteristics of a stream.

In addition to the records of suspended-sediment concentrations, periodic measurements of particle-size distribution of the suspended sediment and bed material also are published.

EXPLANATION OF GROUND-WATER-LEVEL RECORDS

COLLECTION OF THE DATA

Ground-water-level data for 70 observation wells are published in this report. These wells are part of a network of 199 observation wells measured in Wisconsin. Of the 70 wells, 21 are measured by U.S. Geological Survey personnel, 39 by State or County personnel, and 10 by interested area residents.

These data represent water-table and artesian conditions in the principal aquifers of the State. Precipitation is the major climatic factor affecting ground-water levels. Spring and fall are the seasons when the water table is the highest.

An exception to these conditions is in the sandstone aquifer in southeastern Wisconsin where heavy municipal and industrial pumping is causing a continual decline in the water level. Water in this aquifer is under artesian pressure where confined by the overlying Maquoketa Shale.

Water levels in artesian wells in the State are sensitive to major earthquakes. Response to earthquakes worldwide is observed on graphs from water-stage recorders as an instantaneous rise and fall in water level and generally occur within an hour of the initial shock.

Water-level records for 58 wells are obtained from direct measurements with a steel tape; records for 13 are from the graph on a water-stage recorder. Water-level measurements in this report are referenced to the land-surface datum (lsd)--a datum plane approximately at land surface at each well. The altitude of the lsd above the National Geodetic Vertical Datum of 1929 and the height of the measuring point (MP) above or below the lsd is given in each well description. All taped measurements are listed. For wells with recorders, lows are listed for every fifth day and at the end of the month (eom). Normally, water levels are reported to a hundredth of a foot. The absolute value of the depth to water may be in error by a few tenths of a foot, but the error in determining the net change in water level between successive measurements is normally only a hundredth or a few hundredths of a foot.

NOTEWORTHY HYDROLOGIC EVENTS OF 1982

STREAMFLOW

Runoff was generally above normal for the 1982 water year. There were a number of recorded flood peaks that exceeded the 2-year frequency. Peaks in the Chippewa River and Upper Rock River basins in the spring of 1982 were generally between the 5- and 10-year frequency. High base flow was maintained for most streams during the 1982 water year. Recorded low flows were generally greater than the 2-year low-flow discharge.

Streamflow was in the normal to below normal range in the north and northeastern part of the State and above normal for the remainder of the State in the fall. Flows were below normal during the winter. Spring runoff was above normal due to a combination of snowmelt and spring rains, with dry conditions developing in June. Periodic storms during the summer maintained higher than normal flow for most of the summer.

Runoff for the year ranged from 80 to 180 percent of a long-term average (fig. 1). The area of highest runoff was the upper Rock River basin, which was 140-180 percent above normal. The area of lowest runoff was the upper Wisconsin, Wolf and Peshtigo River basins, which were 80 to 100 percent of normal. Monthly and annual flow for the 1982 water year is compared to median discharges for a 65-year base period (fig. 2).

Figure 1. 1982 runoff as percent of long-term average runoff.

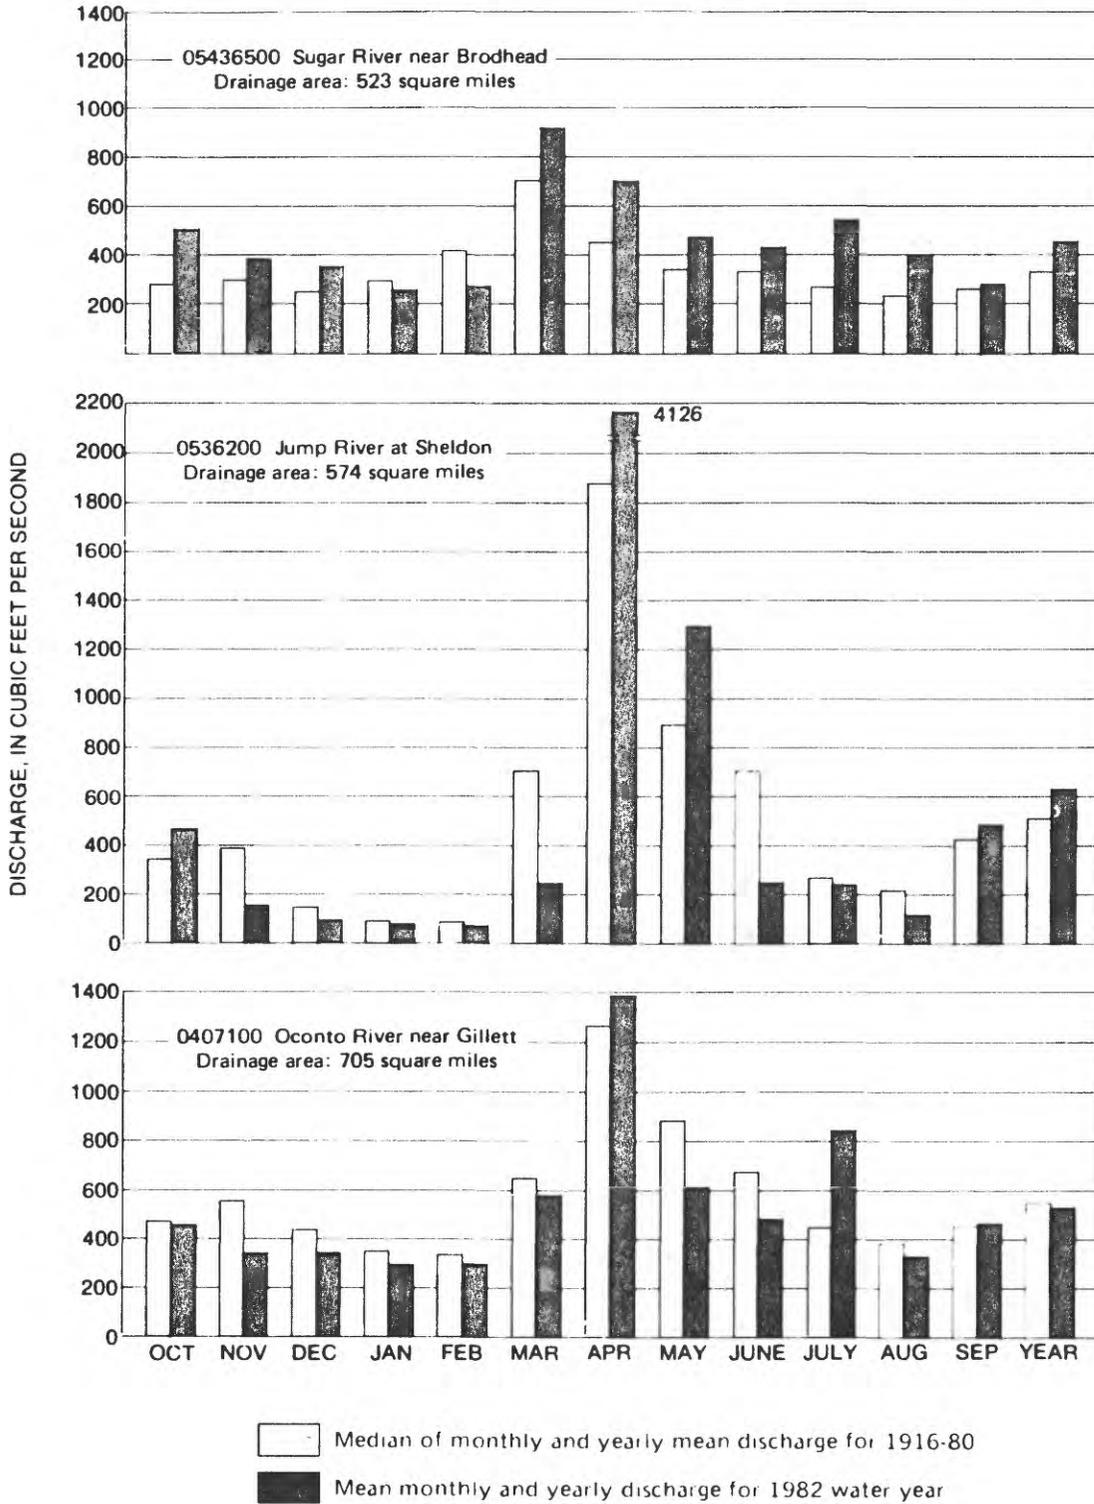

Figure 2. Comparison of discharge at representative gaging stations during 1982 water year with median discharge for 1916-80.

WATER QUALITY

Significant concentrations of the herbicides - atrazine, simazine, prometon, and trifluralin were found in water from the Fox, Manitowoc, Milwaukee, Onion, and Sheboygan Rivers. The organochlorine insecticides - DDD, DDT, DDE, chlordane, endrin, and heptachlor epoxide and the industrial chemical - PCB were found in bed material from the Fox, Manitowoc, Milwaukee, and Sheboygan Rivers.

GROUND-WATER LEVELS

The seasonal level of the water table reflects natural recharge and discharge, and indirectly reflects long-term precipitation trends.

Figure 3 shows how 1982 seasonal water levels relate to normal. Normal is defined as being within one-half of one standard deviation above or below the seasonal mean for the period of record. The months in each season are adjusted so that the spring recharge period includes March, April, and May. Records for 29 wells were used to show areal trends. All measurements during each three-month season were averaged and compared to long-term seasonal means.

We entered the winter (December-February) with the water table at normal levels throughout most of the State. Water levels were above normal in a narrow east-west band across north-central Wisconsin and in south-central Wisconsin. They were below normal at points in the east. In the spring (March-May), levels remained above normal and normal over the same general areas, with only one segment of northeast Wisconsin being below normal. Summer (June-August) levels again displayed a similar pattern. A larger area had above normal water levels, and there were isolated areas (wells) with below normal levels. In the fall (September-November), south-central and north-central Wisconsin remained above normal and two areas on the east coast showed below normal levels.

In summary, during most of the year, water levels were above normal across the north-central part of the State and in the southwest - south-central part. They were in the normal range throughout most of the remainder of Wisconsin. Water levels in Milwaukee, Kewaunee, and Door Counties were below normal much of the year. This is probably caused by pumping from the deep confined aquifer in the Milwaukee area, and is possibly caused by pumping in the Green Bay area in northeast Wisconsin.

STREAMS TRIBUTARY TO LAKE MICHIGAN
04063000 MENOMINEE RIVER NEAR FLORENCE, WI

LOCATION.--Lat 45°57'04", long 88°11'13", in NE 1/4 sec.16, T.41 N., R.31 W., Michigan Meridian, Iron County, Hydrologic Unit 04030108, on left bank 0.5 mi (0.8 km) downstream from confluence of Brule and Michigamme Rivers, 3.5 mi (5.6 km) northeast of Florence, and at mile 117 (188 km).

DRAINAGE AREA.--1,780 mi² (4,610 km²).

PERIOD OF RECORD.--January 1914 to current year. Published as "at Twin Falls near Iron Mountain, MI" 1914-57. Records published for both sites July 1950 to September 1957.

REVISED RECORDS.--WSP 1707: 1953(M). WSP 1911: Drainage area of former site.

GAGE.--Water-stage recorder. Datum of gage is 1,119.23 ft (341.141 m) National Geodetic Vertical Datum of 1929 (levels by Owen Ayres Associates). Prior to July 1950, headwater and tailwater gages and generation data entered hourly in daily log sheets by company employees at the Twin Falls Powerplant of Wiaconsin Electric Power Co., 10.4 mi (16.7 km) downstream.

REMARKS.--Records excellent. Prior to July 1950, discharge determined from powerplant records computed on basis of load-discharge rating of hydroelectric units and rating for tailwater gage during periods of spill. Rating developed by Geological Survey. Flow regulated by powerplants, Michigamme Reservoir, capacity, 119,950 acre-ft (148 km³), and Peavy Pond, capacity, 33,860 acre-ft (41.7 km³), on Michigamme River, and by many smaller reservoirs above station. Several observations of water temperature were made during the year.

AVERAGE DISCHARGE.--68 years, 1,806 ft³/s (51.15 m³/s).

EXTREMES FOR PERIOD OF RECORD.--Maximum discharge, 19,500 ft³/s (552 m³/s) Apr. 26, 1960, gage height, 14.15 ft (4.313 m); minimum, 38 ft³/s (1.08 m³/s) Aug. 21, 1962, Sept. 26, 1975; minimum gage height, 1.18 ft (0.360 m) Aug. 21, 1962, Nov. 4, 1965; minimum daily discharge, 57 ft³/s (1.61 m³/s) Sept. 26, 1975.

EXTREMES FOR CURRENT YEAR.--Maximum discharge, 9,220 ft³/s (261 m³/s) May 9, gage height, 9.21 ft (2.807 m); minimum, 130 ft³/s (3.68 m³/s) Nov. 7, gage height, 1.59 ft (0.485 m); minimum daily, 494 ft³/s (14.0 m³/s) July 3.

STREAMS TRIBUTARY TO LAKE MICHIGAN

04082500 LAKE WINNEBAGO AT OSHKOSH, WI

LOCATION.--Lat 44°00'35", long 88°31'38", in NE 1/4 NE 1/4 sec.25, T.18 N., R.16 E., Winnebago County, Hydrologic Unit 04030203, at 905 Bay Shore Drive, 800 ft (244 m) east of mouth of the upper Fox River.

DRAINAGE AREA.--5,310 mi² (13,750 km²), at lake outlet at Menasha Dam.

PERIOD OF RECORD.--October 1938 to current year in reports of Geological Survey. Records from 1882 to 1938 in files of Geological Survey and Corps of Engineers. A report on Fox River by Corps of Engineers, published as House Document No. 146, 67th Congress, 2nd session, contains semi-monthly records of inflow of Lake Winnebago for the period 1896-1917.

REVISED RECORD.--WDR WI-80-1: Drainage area.

GAGE.--Water-stage recorder. Nonrecording gage read once daily October 1938 to October 1978. Datum of gage is 745.05 ft (227.091 m) mean tide at New York City (levels by Corps of Engineers). Datum of Deuchman gage is 745.00 ft (227.076 m) mean tide at New York City.

REMARKS.--Lake elevations controlled by dams at Menasha and Neenah, which are operated in the interest of navigation. Crests of both dams are at elevation 746.73 ft (227.603 m). Present limits of regulation are from 21 1/4 in. (540 mm) above the crest of Menasha dam to crest during navigation season, plus additional 18 in. (457 mm) below crest during winter. Oshkosh staff gage gives true level of lake, while Deuchman gage readings are affected by loss of head in the channel between lake and dam.

EXTREMES FOR PERIOD OF RECORD.--Maximum gage height observed, 5.33 ft (1.62 m) (Deuchman gage) Nov. 8, 1881, minimum observed, -2.00 ft (-0.61 m) (Deuchman gage) Nov. 28, 1891.

EXTREMES FOR CURRENT YEAR.--Maximum gage height, 3.80 ft (1.158 m) Aug. 4, local condition due to seiche and precipitation; minimum, 0.26 ft (0.079 m) Mar. 12.

WATER-DISCHARGE RECORDS

PERIOD OF RECORD.--January 1902 to current year. Prior to January 1910, monthly discharge only, published in WSP 1308. Prior to October 1939, published as "near St. Croix Falls."

REVISED RECORDS.--WSP 1115: 1929.

GAGE.--Water-stage recorder and crest-stage gage. Datum of gage is 689.94 ft (210.294 m) National Geodetic Vertical Datum of 1929. Prior to July 1905, gage heights and discharge measurements were used by Loweth and Wolff, consulting engineers of St. Paul, Minn., to determine the flow. July 1905 to February 1940, records were computed from power generation at the St. Croix Falls Powerplant. February 1940 to Sept. 30, 1979, water-stage recorder at site 300 ft (91 m) downstream at same datum.

REMARKS.--Records are good. Discharges for periods of no gage-height record, Jan. 8 to Feb. 1, Apr. 18-21, and June 15 to Aug. 18, furnished by Northern States Power Co. Diurnal fluctuation caused by St. Croix Falls Powerplant 1,500 ft (457 m) upstream.

AVERAGE DISCHARGE.--80 years, 4,206 ft³/s (119.1 m³/s), 9.15 in/yr (232 mm/yr).

EXTREMES FOR PERIOD OF RECORD.--Maximum discharge, 54,900 ft³/s (1,550 m³/s) May 8, 1950, gage height, 25.19 ft (7.678 m); minimum daily, 75 ft³/s (2.12 m³/s) July 17, 1910.

EXTREMES FOR CURRENT YEAR.--Maximum discharge, 30,600 ft³/s (867 m³/s) Apr. 19, gage height, 14.34 ft (4.371 m); minimum daily, 1,410 ft³/s (39.9 m³/s) Dec. 17.

WISCONSIN RIVER BASIN

05400760 WISCONSIN RIVER AT WISCONSIN RAPIDS, WI

LOCATION.--Lat 44°23'41", long 89°49'31", in SW 1/4 sec.8, T.22 N., R.6 E., Wood County, Hydrologic Unit 07070003, at Consolidated Water Power Company, 0.2 mi (0.3 km) upstream from U.S. Highway 13 bridge in Wisconsin Rapids.

DRAINAGE AREA.--5,420 mi² (14,040 km²).

PERIOD OF RECORD.--May 1914 to March 1950 (published as "near Nekoosa"), October 1957 to current year.

REVISED RECORDS.--WSP 1308: 1915(M).

GAGE.--Water-stage recorders on headwater and tailwater. Elevation of powerplant pond is 1,010 ft (308 m) and datum of powerplant gages is 0.00 ft (0.00 m) National Geodetic Vertical Datum of 1929 (levels by Wisconsin Valley Improvement Co.). May 1914 to March 1950, at site 9.6 mi (15.4 km) downstream at different datum. March 1950 to Sept. 30, 1981, at Centralia Powerplant at Nekoosa Papers, Inc., 2.6 mi (4.2 km) downstream. March 1950 to Dec. 31, 1973, datum was 887.83 ft (270.611 m) National Geodetic Vertical Datum. Jan. 1, 1974, changed to present datum.

REMARKS.--Records good. Discharge computed from powerplant records on basis of load-discharge rating of hydroelectric units as developed by manufacturer and tainter-gate ratings based on theoretical formulas. Flow regulated by 20 reservoirs and many powerplants above station. Water diverted periodically from pond of Wisconsin Rapids powerplant into Cranberry Creek, a tributary of Yellow River, for cranberry culture. These diversions, in cubic feet per second, for water year October 1981 to September 1982, were as follows:

DISCHARGE AT PARTIAL-RECORD STATIONS AND MISCELLANEOUS SITES

CREST-STAGE PARTIAL-RECORD STATIONS

The following table contains annual maximum discharges for crest-stage stations. A crest-stage gage is a device which will register the peak stage occurring between inspections of the gage. A stage-discharge relation for each gage is developed from discharge measurements made by indirect measurements of peak flow or by current meter. The date of the maximum discharge is not always certain but is usually determined by comparison with nearby continuous-record stations, weather records, or local inquiry. Only the maximum discharge for each water year is given. Information on some lower floods may have been obtained but is not published herein. The years given in the period of record represent water years for which the annual minimum has been determined.

DEFINITION OF TERMS

Terms used in this report with reference to streamflow, water-quality, and other hydrologic data are defined below. See also the conversion table for inch-pound units and International System (SI) units on the inside of the back cover.

Acre-foot (acre-ft) is the quantity of water required to cover 1 acre to a depth of 1 foot. It is the equivalent of 43,560 cubic feet, 325,851 gallons, or 1,233 cubic meters.

Aquifer is a geologic formation, group of formations, or part of a formation that contains sufficient saturated permeable material to yield significant quantities of water to wells and springs.

Bacteria are microscopic, unicellular organisms, typically spherical, rod-like, or spiral and threadlike in shape, and often clumped into colonies. Some bacteria cause disease; others perform essential roles in the natural recycling of materials such as decomposing organic matter into forms available for reuse by plants.

Fecal coliform bacteria are present in the intestines of warmblooded animals and are used to determine the sanitary quality of water. They are defined as those organisms that produce blue colonies within 24 hours when incubated at $44.5^{\circ}\text{C} \pm 0.2^{\circ}\text{C}$ on FC culture medium. Their concentrations are expressed as number of colonies per 100 ml of sample.

Fecal streptococci bacteria are also found in the intestines of warmblooded animals. Their presence in water is used to verify fecal pollution. They are characterized as gram-positive, spherical bacteria capable of growth in brain-heart infusion broth. They are defined as those organisms that produce red or pink colonies within 48 hours at $35^{\circ}\text{C} \pm 1.0^{\circ}\text{C}$ on M-enterococcus culture medium. Their concentrations are expressed as number of colonies per 100 ml of sample.

Bed material is the unconsolidated material at the bottom of a streambed, lake, pond, reservoir, or estuary.

Biochemical oxygen demand (BOD) measures the quantity of dissolved oxygen, in milligrams per liter, used by microorganisms for the decomposition of organic matter.

Cfs-day is the volume of water produced by a flow of 1 cubic foot per second for 24 hours. It is the equivalent of 86,400 cubic feet, 1.9835 acre-feet, 646,000 gallons, or 2,447 cubic meters.

Control is a feature downstream from a gage that determines the stage-discharge relation at the gage. The control may be a natural constriction of the channel, an artificial structure, or a uniform cross section over a long reach of the channel.

Cubic feet per second per square mile (CFSM) is the average number of cubic feet of water flowing per second from each square mile of area drained, assuming that the runoff is distributed uniformly in time and area.

Cubic foot per second (ft^3/s) represents a volume of 1 cubic foot of water passing a given point during 1 second and is the equivalent of 7.48 gallons per second, 448.8 gallons per minute, or 0.02832 cubic meters per second.

Discharge is the volume of fluid or mass of suspended sediment passing a given point in a given period of time.

Mean discharge (MEAN) is the arithmetic average of all daily mean discharges for a specific period of time.

Instantaneous discharge is the discharge at a particular time.

Dissolved is an operational definition used by Federal and State agencies collecting water data as that material in a water sample which passes through a 0.45 μm membrane filter. Determinations of "dissolved" constituents are made on subsamples of the filtrate.

Drainage area of a stream at a specified location is measured in a horizontal plane and constitutes an area enclosed by a topographic divide from which surface runoff above the specified point drains by gravity into the stream. Values of the drainage areas given herein include closed basins and noncontributing areas within the basin, as noted.

Gage height (G.H.) is the water-surface elevation referred to some arbitrary gage datum. Gage height is often used interchangeably with the general term "stage", although gage height is more appropriate when referring to a reading on a gage.

Gaging station is a particular site on a stream or lake where systematic hydrologic data are collected.

Hardness is a physical-chemical characteristic of water that is attributable principally to the presence of calcium and magnesium and is expressed as calcium carbonate (CaCO_3). Hardness is commonly recognized by the increased quantity of soap required to produce lather.

Hydrologic unit designates part or all of a surface-drainage basin delineated by the Office of Water Data Coordination; each hydrologic unit is identified by an 8-digit number.

Micrograms per gram ($\mu\text{g}/\text{g}$) indicates the concentration of a chemical constituent as the mass (micrograms) of that constituent per unit mass (gram) of sediment.

Micrograms per kilogram ($\mu\text{g}/\text{kg}$) indicates the concentration of a chemical constituent as mass (micrograms) of that constituent per unit mass (kilogram) of sediment.

Micrograms per liter ($\mu\text{g}/\text{L}$) indicates the concentration of a chemical constituent as the mass (micrograms) of that constituent per unit volume (liter) of water. One thousand micrograms per liter is equivalent to 1 milligram per liter.

Milligrams per liter (mg/L) indicates the concentration of a chemical constituent or suspended sediment as the mass (milligrams) per unit volume (liter) of water.

National Geodetic Vertical Datum of 1929 (NGVD) is a geodetic datum derived from a general adjustment of the first order level nets of both the United States and Canada. It was formerly called "Sea Level Datum of 1929" or "mean sea level" in this series of reports. Although the datum was derived from the average sea level over a period of many years at 26 tide stations along the Atlantic, Gulf of Mexico, and Pacific Coasts, it does not necessarily represent local mean sea level at any particular place.

Partial-record station is a site for the systematic collection of limited streamflow or water-quality data over a period of years.

Particle size is measured as the diameter, in millimeters (mm), of suspended sediment and bed material determined by sieve or sedimentation methods. Sedimentation methods (pipet, bottom-withdrawal tube, visual-accumulation tube) measure the fall diameter of particles in distilled water (chemically dispersed) or native water (surface water at the time and point of sampling).

Particle-size classification for this report is based on recommendations of the American Geophysical Union Subcommittee on Sediment Terminology. The classification is as follows:

<u>Classification</u>	<u>Size (mm)</u>	<u>Method of analysis</u>
Clay.....	0.00024 - 0.004	Sedimentation.
Silt.....	.004 - .062	Sedimentation.
Sand.....	.062 - 2.0	Sedimentation or sieve.
Gravel.....	2.0 - 64.0	Sieve.

Pesticides are chemical compounds used to control undesirable plants and animals. They include insecticides, miticides, fungicides, herbicides, and rodenticides. Insecticides and herbicides control insects and plants respectively and are the two categories reported.

Picocurie (PCi) is one trillionth (1×10^{-12}) of a curie (Ci). A curie is the amount of radioactivity that yields 3.7×10^{10} disintegrations per second. A picocurie yields 2.22 disintegrations per minute.

Polychlorinated biphenyls (PCB's) are industrial chemicals composed of biphenyl compounds containing various amounts of chlorine. Their chemical structure is similar to the organochlorine insecticides.

Polychlorinated naphthalenes (PCN's) are industrial chemicals composed of naphthalene compounds containing various amounts of chlorine. Their chemical structure is similar to the organochlorine insecticides.

Recoverable from bottom material is the amount of a given constituent that is in solution after a sample of bottom material has been digested by an acid or mixture of acids that results in dissolution of only readily soluble substances. Complete dissolution of all bottom material usually is not achieved by the digestion treatment and thus the determination represents less than the total amount of the constituent in the sample. To achieve comparability of analytical data, equivalent digestion procedures would be required of all laboratories performing such analyses because different digestion procedures are likely to produce different analytical results.

Runoff in inches (IN, in) indicates the depth of water that would cover a drainage area if all runoff for a given time period were uniformly distributed.

Sediment originates mostly from disintegrated rocks and is transported by, suspended in, and deposited by water; it includes chemical and biochemical precipitates and decomposed organic material such as humus. Topography, geology, soil type, land cover, land use, quantity and intensity of precipitation, and other environmental factors influence the quantity, characteristics, and cause of sediment in streams.

Suspended sediment is sediment maintained in suspension by turbulent currents or as a colloid.

Suspended-sediment discharge is the quantity of suspended sediment passing through a stream cross section in a unit of time. It is computed by multiplying water discharge times suspended-sediment concentration times 0.0027.

Suspended-sediment concentration is the velocity-weighted concentration of suspended sediment in a sample zone (from the water surface to approximately 0.3 ft above the streambed) and is expressed as milligrams of dry sediment per liter of water-sediment mixture (mg/L).

Mean concentration is the time-weighted concentration of suspended sediment passing through a stream cross section during a 24-hour period.

Sodium-adsorption ratio (SAR) expresses the relative activity of sodium ions in exchange reactions with soil.

Solute is any substance dissolved in water.

Specific conductance is a measure of the ability of water to conduct electrical current and is expressed in micromhos per centimeter at 25°C. It is related to the number and specific types of ions in solution, and is useful for approximating the concentration of dissolved solids in the water. Commonly, the concentration of dissolved solids mg/L is about 65 percent of the specific conductance.

Stage-discharge relation correlates height (stage) and the volume of water flowing in a channel per unit of time.

Streamflow uniquely describes discharge in the natural channel of a surface stream course as opposed to the term "discharge", which can be applied to the flow of a canal. Unlike the term "runoff", streamflow may be applied to discharge whether it is affected by diversion or regulation or not.

Suspended, recoverable is the amount of a given constituent that is in solution after the part of a water-sediment sample retained on a 0.45 μm membrane filter has been digested by dilute acid that results in dissolution of only readily soluble substances. Complete dissolution of all the particulate matter usually is not achieved by the digestion treatment and thus the determination represents something less than the "total" amount of the constituent present in the sample. To achieve comparability of analytical data, equivalent digestion procedures would be required of all laboratories performing such analyses because different digestion procedures are likely to produce different analytical results.

Determinations of "suspended, recoverable" constituents are made either by analyzing portions of the material collected on the filter or, more commonly, by difference, based on determinations of dissolved and total recoverable concentrations of the constituent.

Suspended, total is the total amount of a given constituent in the part of a water-sediment sample that is retained on a 0.45 μm membrane filter. This term is used only when the analytical procedure assures measurement of at least 95 percent of the constituent determined. A knowledge of the expected form of the constituent in the sample, as well as the analytical methodology used, is required to determine when the results should be reported as "suspended, total."

Determinations of "suspended, total" constituents are made either by analyzing portions of the material collected on the filter or, more commonly, by difference, based on determinations of dissolved and total concentrations of the constituent.

Thermograph is an instrument that continuously and automatically records temperature.

Tons per acre-foot indicates the dry weight of a constituent in 1 acre-foot of water. It is computed by multiplying the concentration in milligrams per liter by 0.00136.

Tons per day is the measure of a substance that passes a stream section in solution or suspension during a 24-hour period. It is computed by multiplying the concentration of the substance (mg/L) by 0.0027 times the discharge of the stream (cfs).

Total is the total amount of a given constituent in a water-sediment sample, regardless of the constituent's physical or chemical form. This term is used only when the analytical procedure assures measurement of at least 95 percent of the constituent present in both the dissolved and suspended phases of the sample. A knowledge of the expected form of the constituent in the sample, as well as the analytical methodology used, is required to judge when the results should be reported as "total." The term indicates the sample consists of a water-sediment mixture and that the analytical method determines all of the constituent in the sample.

Total, recoverable is the amount of a given constituent that is in solution after a water-sediment sample has been digested by dilute acid resulting in dissolution of only readily soluble substances. Complete dissolution of all particulate matter usually is not achieved, thus the determination represents something less than the "total" amount of the constituent present in the dissolved and suspended phases of the sample. To achieve comparability of analytical data, equivalent digestion procedures would be required of all laboratories performing such analyses because different digestion procedures are likely to produce different analytical results.

Total in bottom material is the total amount of a given constituent in a representative sample of bottom material. This term is used only when the analytical procedure assures measurement of at least 95 percent of the constituent determined. A knowledge of the expected form of the constituent in the sample, as well as the analytical methodology used, is required to judge when the results should be reported as "total in bottom material."

WDR is the abbreviation for "Water-Data Report" used in the summary REVISIONS paragraph to indicate previously published State annual basic data reports.
